

## X.5 Sustainable Dev<sup>t</sup>: Ecology & Economic Progress

### # Dev<sup>t</sup> & Sustainable Dev<sup>t</sup>

→ Dev<sup>t</sup> (D) : vector of desirable social objectives deemed fit by dev<sup>t</sup> agencies, state etc. ( $\Rightarrow$  open to ethical debate)  
It may include (not exhaustively)  $\rightarrow$  education,  $\uparrow$  per capita Y, improvement in health & nutritional status, access to basic freedoms etc.

Sustainable dev<sup>t</sup>  $\Rightarrow$  when vector D does not decrease overtime.

Probs with def<sup>n</sup>: (1) Assumes infinite time horizon. Policy decisions, however, are taken in a finite space

(2) Does not make a distinction b/w strong sustainability ( $\frac{dD}{dt} > 0$  for each and every time period) vs weak sustainability (whether trend of  $\frac{dD}{dt}$  must be  $> 0$ ) or PDV benefits must exceed costs

→ Idea of sustainability is better to be interpreted in its weak form ( $\frac{dD}{dt}$  is 'generally'  $> 0$  over selected time horizon)

→ Underly<sup>g</sup> idea of weak sustainability is ass<sup>n</sup> that there has been some degradation or extinction of resources.

$\therefore$  Sustainable dev<sup>t</sup>  $\Rightarrow$

(a) vector D is non- $\downarrow$  overtime.

(b) Elements of D open to debate

(c) Relevant time horizon for ~~pro~~ policy decision mak<sup>g</sup> is indeterminate

(d) Intergenerational objectives considered.

Yet, there exist several probs. with the generality of the def.

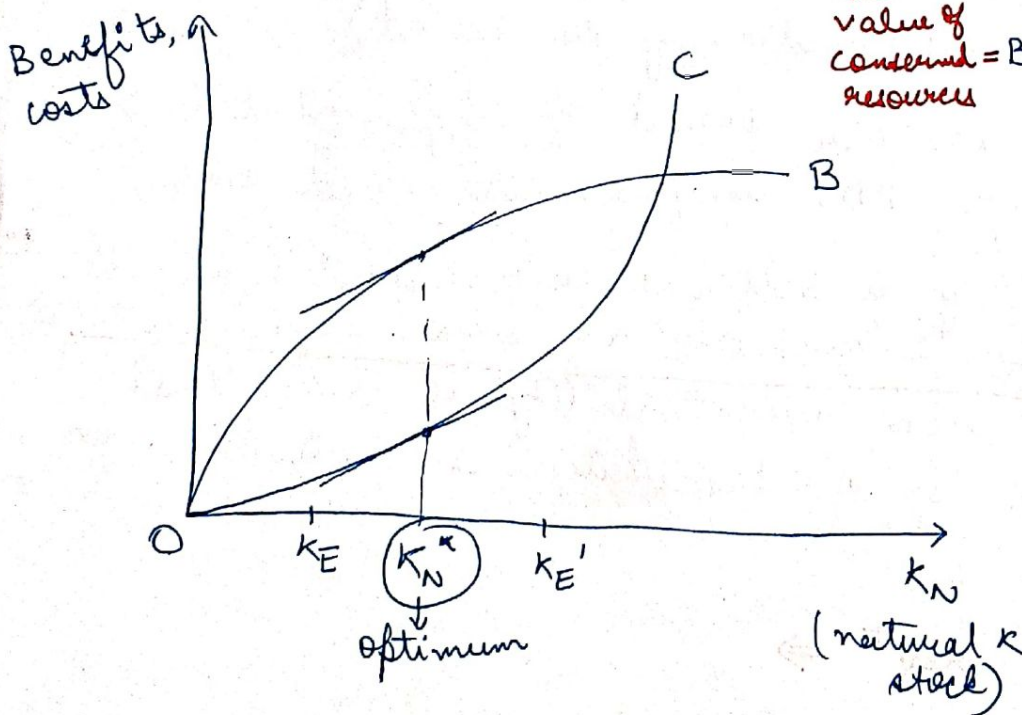

# # CONDITIONS FOR ACHIEVING SUSTAINABLE

Dev<sup>t</sup> (Debatable def<sup>n</sup> conditions)

Key necessary condition -  $\longleftrightarrow$  natural K stock

defined broadly to include all qty & quality natural resources  $\leftarrow$  quality  
 non - ve  $\Delta$  in stock of natural resources & environmental quality  
 (conservation + improvements are welcome)  
 (World Commission Report, 1987)

However,  $\Delta$  Natural K stock has advantages + prod<sup>n</sup>,  
 $C^N$  (eco<sup>d</sup> as a whole)  $\Rightarrow$  a cost-Benefit analysis is essential to determine optimum stock.

=  $\frac{\text{use value}}{\downarrow}$  +  $\frac{\text{non-use value}}{\downarrow}$   
 for wildlife obs, recreation, scientific study, etc)  
 pollution control, waste sink  
 existence value to non-users

C = as  $K_N \uparrow \Rightarrow \exists$  ↑ costs in the form of foregone benefits from not conserve the environment. (eg dev<sup>t</sup> foregone by not doing deforestation)

If  $K_N < K_N^* \rightarrow$  Beneficial to ↑ stock by ↓ degradation  
 $K_N > K_N^* \rightarrow$  Beneficial to reduce stock by ↑ degradation

∴ Follow the def<sup>n</sup> of sustainable dev<sup>t</sup>, maintenance is required iff we are at  $K_N^*$  or ↑ is reqd. iff we are to the left of  $K_N^*$ . why doesn't the def<sup>n</sup> then also talk about ↓ of Natural K stock (pts. to right of  $K_N^*$ )? then why is conservation of exist<sup>g</sup> stock imp.?

- 1.) For dev<sup>g</sup> countries generally ~~of~~ →  $K_N < K_N^*$
- 2.) The cost benefit analysis only compares 'value' of increas<sup>g</sup> natural resources with opp. cost of degrad<sup>g</sup> them & us<sup>g</sup> them for ↑<sup>g</sup> dev<sup>t</sup>. It does not consider their multifunctionality into integrated life support system.

∴ Even if a ctry can afford degradation (to the right of  $K_N^*$ ) there are risks of doing so as

- (a) Imperfect understand<sup>g</sup> of  $K_N$  as life support system
- (b) Even if degradation was reversible, there exists low capability to substitute/reverse it later
- (c) ∃ losses due to irreversibility.

∴ when uncertainty + irreversibility exist ⇒ rational & sensible exist<sup>g</sup> stock until a clearer determination of optimal stock can be made

3.) use of concepts of willingness to pay (for ↑ in size of exist<sup>g</sup> asset) and willingness to accept (for ↓ in \_\_\_\_\_) measures of benefit.

Eco<sup>c</sup> theory ⇒ willingness to pay + a small gain = accept on giv<sup>g</sup> up a small amt. of asset.  
(compensation)

h/w the two. Compensation<sup>reqd.</sup> is much higher. (4)

why? Exist<sup>d</sup> stock is the reference point  $\Rightarrow$

Prospect theory  $\rightarrow$  attitudes to give up someth<sup>g</sup> we ~~has~~ already have is diff. from when  $\exists$  prospect of gain.

$\hookrightarrow$  Benefit curve is "kinked" at exist<sup>d</sup> stock.

If exist<sup>d</sup> stock represents the kink  $\Rightarrow$  optimal stock = exist<sup>d</sup> k stock ( $K_n$ )

$\therefore$  The def<sup>n</sup> of sustainable dev<sup>t</sup> that calls for a constant k stock  $\Rightarrow$  a higher valuation should be placed on reduction of exist<sup>d</sup> k stock ( $\because$  B curve is steeper before  $K_E$ ) than  $\downarrow$  it  $\therefore$  conservation is imp. & depends on  $K_E$ . (which is ipso facto =  $K_N$ )
